## Inferences Based on a Single Sample Tests of Hypothesis

8.2 The test statistic is used to decide whether or not to reject the null hypothesis in favor of the alternative hypothesis.
8.4 A Type I error is rejecting the null hypothesis when it is true.

A Type II error is accepting the null hypothesis when it is false.
$\alpha=$ the probability of committing a Type I error.
$\beta=$ the probability of committing a Type II error.
8.6 We can compute a measure of reliability for rejecting the null hypothesis when it is true. This measure of reliability is the probability of rejecting the null hypothesis when it is true which is $\alpha$. However, it is generally not possible to compute a measure of reliability for accepting the null hypothesis when it is false. We would have to compute the probability of accepting the null hypothesis when it is false, $\beta$, for every value of the parameter in the alternative hypothesis.
8.8 a. The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z>1.645$.
b. The rejection region requires $\alpha=.10$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{10}=1.28$. The rejection region is $z>1.28$.
c. The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z<-1.645$.
d. The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z_{.025}=1.96$. The rejection region is $z>1.96$ or $z<-1.96$.
8.10 Let $\mu=$ mean listening time of 16 -month-old infants exposed to non-meaningful monosyllabic words. To see if the mean listening time of 16 -month-old infants is different from 8 seconds, we test:

$$
\begin{aligned}
& H_{0}: \mu=8 \\
& H_{\mathrm{a}}: \mu \neq 8
\end{aligned}
$$

8.12 Let $\mu=$ mean calories in Virginia school lunches. To determine if the average caloric content of Virginia school lunches dropped from 863 calories, we test:

$$
\begin{aligned}
& H_{0}: \mu=863 \\
& H_{\mathrm{a}}: \mu<863
\end{aligned}
$$

8.14 Let $p=$ proportion of college presidents who believe that their online education courses are as good as or superior to courses that utilize traditional face-to-face instruction. To determine if the claim made by the Sloan Survey is correct, we test:

$$
H_{0}: p=.60
$$

a. Let $\mu=$ mean pain intensity reduction for trauma patients who receive normal analgesic care. To determine if the change in mean pain intensity for trauma patients who receive normal analgesic care is smaller than that for patients who received VRH training, we test:

$$
\begin{aligned}
& H_{0}: \mu=10 \\
& H_{\mathrm{a}}: \mu<10
\end{aligned}
$$

b. A Type I error is rejecting the null hypothesis when it is true. For this test, a Type I error would be concluding the change in mean pain intensity for trauma patients who receive normal analgesic care is smaller than that for patients who received VRH training when, in fact, the change is not smaller.
c. A Type II error is accepting the null hypothesis when it is false. For this test, a Type II error would be concluding the change in mean pain intensity for trauma patients who receive normal analgesic care is not smaller than that for patients who received VRH training when, in fact, the change is smaller.
8.18 a. A Type I error is rejecting the null hypothesis when it is true. In a murder trial, we would be concluding that the accused is guilty when, in fact, he/she is innocent.

A Type II error is accepting the null hypothesis when it is false. In this case, we would be concluding that the accused is innocent when, in fact, he/she is guilty.
b. Both errors are bad. However, if an innocent person is found guilty of murder and is put to death, there is no way to correct the error. On the other hand, if a guilty person is set free, he/she could murder again.
c. In a jury trial, $\alpha$ is assumed to be smaller than $\beta$. The only way to convict the accused is for a unanimous decision of guilt. Thus, the probability of convicting an innocent person is set to be small.
d. In order to get a unanimous vote to convict, there has to be overwhelming evidence of guilt. The probability of getting a unanimous vote of guilt if the person is really innocent will be very small.
e. If a jury is prejudiced against a guilty verdict, the value of $\alpha$ will decrease. The probability of convicting an innocent person will be even smaller if the jury is prejudiced against a guilty verdict.
f. If a jury is prejudiced against a guilty verdict, the value of $\beta$ will increase. The probability of declaring a guilty person innocent will be larger if the jury is prejudiced against a guilty verdict.
8.20 In a one-tailed test, the alternative hypothesis specifies that the population parameter is strictly greater than some value or strictly less than some value, but not both. In a two-tailed test, the alternative hypothesis specifies that the population parameter is either greater than or less than some value.
8.22 For values of the test statistic that fall in the rejection region, $H_{0}$ is rejected. The rejection region will include values of the test statistic that would be highly unusual if the null hypothesis were true.

For values of the test statistic that do not fall in the rejection region, $H_{0}$ would not be rejected. The values of the test statistic that would not fall in the rejection region would be those values that would not be unusual if the null hypothesis were true.
8.24 a. $\quad H_{0}: \mu=.36$

$$
H_{\mathrm{a}}: \mu<.36
$$

The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{.323-.36}{\frac{\sqrt{.034}}{\sqrt{64}}}=-1.61$
The rejection region requires $\alpha=.10$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{10}=1.28$. The rejection region is $z<-1.28$.

Since the observed value of the test statistic falls in the rejection region ( $z=-1.61<-1.28$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the mean is less than . 36 at $\alpha=.10$.
b. $\quad H_{0}: \mu=.36$
$H_{\mathrm{a}}: \mu \neq .36$

The test statistic is $z=-1.61$ (see part a).
The rejection region requires $\alpha / 2=.10 / 2=.05$ in the each tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z<-1.645$ or $z>1.645$.

Since the observed value of the test statistic does not fall in the rejection region ( $z=-1.61 \nless-1.645$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the mean is different from . 36 at $\alpha=.10$.
8.26 Let $\mu=$ mean student-driver response five months after a safe-driver presentation.
a. To determine if the true mean student-driver response five months after a safe-driver presentation is larger than 4.7, we test,

$$
H_{0}: \mu=4.7
$$

$H_{\mathrm{a}}: \mu>4.7$
b. The test statistic is $z=\frac{\bar{x}-\mu}{\sigma_{\bar{x}}} \approx \frac{4.89-4.7}{\frac{1.62}{\sqrt{258}}}=2.78$.
c. The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z>1.645$.
d. Since the observed value of the test statistic falls in the rejection region ( $z=2.78>1.645$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the true mean student-driver response five months after a safe-driver presentation is greater than 4.7 at $\alpha=.05$.
e. Yes. We rejected $H_{0}$, that the mean response was equal to 4.7 in favor of $H_{a}$, that the mean response was greater than 4.7.
f. No. There were 258 responses. The Central Limit Theorem indicates that the distribution of $\bar{x}$ is approximately normal, regardless of the original distribution, as long as the sample size is sufficiently large.
8.28 a. The rejection region requires $\alpha=.01$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{.01}=2.33$. The rejection region is $z<-2.33$.
b. The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{19.3-20}{\frac{11.9}{\sqrt{46}}}=-.40$
c. Since the observed value of the test statistic does not fall in the rejection region ( $\mathrm{z}=-.40 \nless-2.33$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the mean number of latex gloves used per week by hospital employees diagnosed with a latex allergy from exposure to the powder on latex gloves is less than 20 at $\alpha=.01$.
8.30 Let $\mu=$ mean heart rate during laughter.
a. To determine if the true mean heart rate during laughter exceeds 71 beats/minute, we test:

$$
\begin{aligned}
& H_{0}: \mu=71 \\
& H_{\mathrm{a}}: \mu>71
\end{aligned}
$$

b. The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z>1.645$.
c. The test statistic is $z=\frac{\bar{x}-\mu_{o}}{\sigma_{\bar{x}}} \approx \frac{73.5-71}{\frac{6}{\sqrt{90}}}=3.95$
d. Since the observed value of the test statistic falls in the rejection region ( $z=3.95>1.645$ ). $H_{0}$ is rejected. There is sufficient evidence to indicate the true mean heart rate during laughter exceeds 71 beats/minute at $\alpha=.05$.
8.32 To determine if the area sampled is grassland, we test:

$$
\begin{aligned}
& H_{0}: \mu=220 \\
& H_{\mathrm{a}}: \mu \neq 220
\end{aligned}
$$

The test statistic is $z=\frac{\bar{x}-\mu_{o}}{\sigma_{\bar{x}}}=\frac{225-220}{\frac{20}{\sqrt{100}}}=2.50$
The rejection region requires $\alpha / 2=.01 / 2=.005$ in each tail of the $z$ distribution. From
Table IV, Appendix A, $z .005=2.58$. The rejection region is $z>2.58$ or $z<-2.58$.
Since the observed value of the test statistic does not fall in the rejection region $(z=2.50 \ngtr$ 2.58). $H_{0}$ is not rejected. There is insufficient evidence to indicate the true mean lacunarity measurements is different from 220 at $\alpha=.01$. There is insufficient evidence to indicate that the sampled area is not grassland.
8.34 a. Using MINITAB, some preliminary calculations are:

## Descriptive Statistics: Heat

| Variable | N | Mean | StDev | Minimum | Q1 | Median | Q3 | Maximum |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Heat | 67 | 11066 | 1595 | 8714 | 9918 | 10656 | 11842 | 16243 |

To determine if the mean heat rate of gas turbines augmented with high pressure inlet fogging exceeds $10,000 \mathrm{~kJ} / \mathrm{kWh}$, we test:

$$
\begin{aligned}
& H_{0}: \mu=10,000 \\
& H_{\mathrm{a}}: \mu>10,000
\end{aligned}
$$

The test statistic is $z=\frac{\bar{x}-\mu_{o}}{\sigma_{\bar{x}}}=\frac{11,066-10,000}{\frac{1595}{\sqrt{67}}}=5.47$
The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z>1.645$.

Since the observed value of the test statistic falls in the rejection region ( $z=5.47>1.645$ ). $H_{0}$ is rejected. There is sufficient evidence to indicate the true mean heat rate of gas turbines augmented with high pressure inlet fogging exceeds $10,000 \mathrm{~kJ} / \mathrm{kWh}$ at $\alpha=.05$.
b. A Type I error is rejecting $H_{0}$ when $H_{0}$ is true. In this case, it would be concluding that the true mean heat rate of gas turbines augmented with high pressure inlet fogging exceeds $10,000 \mathrm{~kJ} / \mathrm{kWh}$ when, in fact, it does not.

A Type II error is accepting $H_{0}$ when $H_{0}$ is false. In this case, it would be concluding that the true mean heat rate of gas turbines augmented with high pressure inlet fogging does not exceed $10,000 \mathrm{~kJ} / \mathrm{kWh}$ when, in fact, it does.
8.36 Let $\mu=$ mean DOC value of all Wisconsin lakes. Using MINITAB, the descriptive statistics are:

## Descriptive Statistics: DOC

| Variable | N | Mean | StDev | Minimum | Q1 | Median | Q3 | Maximum |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| DOC | 25 | 14.52 | 12.96 | 2.40 | 4.15 | 13.20 | 19.10 | 56.90 |

To determine if the sample is representative of all Wisconsin's lakes for DOC, we test:

$$
\begin{aligned}
& H_{0}: \mu=15 \\
& H_{\mathrm{a}}: \mu \neq 15
\end{aligned}
$$

The test statistic is $z=\frac{\bar{x}-\mu_{o}}{\sigma_{\bar{x}}} \approx \frac{14.52-15}{\frac{12.96}{\sqrt{25}}}=-0.19$
The rejection region requires $\alpha / 2=.10 / 2=.05$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z>1.645$ or $z<-1.645$.

Since the observed value of the test statistic does not fall in the rejection region ( $z=-.19 \nless-1.645$ ). $H_{0}$ is not rejected. There is insufficient evidence to indicate the true mean DOC value is different from 15 at $\alpha=.10$. Thus, we can conclude that there is no evidence to indicate the sample is not representative of the entire population.
8.38 The observed significance level or $p$-value of a test is the probability of observing your test statistic or anything more unusual, given $H_{0}$ is true. The value of $\alpha$ is the significance level of a test. It is the probability of rejecting $H_{0}$ when $H_{0}$ is true.
8.40 We will reject $H_{0}$ if the $p$-value $<\alpha$.
a. $.06 \nless .05$, do not reject $H_{0}$.
b. $.10 \varangle .05$, do not reject $H_{0}$.
c. $.01<.05$, reject $H_{0}$.
d. $.001<.05$, reject $H_{0}$.
e. $.251 \nless .05$, do not reject $H_{0}$.
f. $.042<.05$, reject $H_{0}$.
8.42 The smallest value of $\alpha$ for which the null hypothesis would be rejected is just greater than . 06 .

$$
p \text {-value }=P(z \geq 2.17)+P(z \leq-2.17)=(.5-.4850) 2=.0300 \text { (using Table IV, Appendix A) }
$$

First, find the value of the test statistic:

$$
\begin{aligned}
z & =\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{10.7-10}{3.1 / \sqrt{50}}=1.60 \\
p \text {-value } & =P(z \leq-1.60 \text { or } z \geq 1.60)=2 P(z \geq 1.60)=2(.5-.4452)=2(.0548)=.1096
\end{aligned}
$$

There is no evidence to reject $H_{0}$ for $\alpha \leq .10$.
8.48 a. From the printout, the $p$-value is $p=.003$. The $p$-value measures the probability of observing your test statistic or anything more unusual if $H_{0}$ is true.
b. Sine the $p$-value is less than $\alpha(p=.003<.05), H_{0}$ is rejected. There is sufficient evidence to indicate the true mean student-driver response five months after a safedriver presentation is greater than 4.7 at $\alpha=.05$. This agrees with the answer to Exercise 8.26c.
a. From Exercise $8.28, z=-.40$. The $p$-value is $p=P(z \leq-.40)=.5-.1554=.3446$ (using Table IV, Appendix A).
b. The $p$-value is $p=.3446$. Since the $p$-value is greater than $\alpha=.01, H_{0}$ is not rejected. There is insufficient evidence to indicate the mean number of latex gloves used per week by hospital employees diagnosed with a latex allergy from exposure to the powder on latex gloves is less than 20 at $\alpha=.01$.
8.52 Let $\mu=$ mean emotional empathy score for females.
a. To test whether female college students score higher than 3.0 on the emotional empathy scale, we test:

$$
\begin{aligned}
& H_{0}: \mu=3.0 \\
& H_{a}: \mu>3.0
\end{aligned}
$$

b. The test statistic is $z=\frac{\bar{x}-\mu_{o}}{\sigma_{\bar{x}}} \approx \frac{3.28-3.0}{\frac{.5}{\sqrt{30}}}=3.07$
c. The $p$-value is $p=P(z \geq 3.07)=.5-.4989=.0011$.
d. Since the $p$-value is less than $\alpha=.01(p=.0011<.01), H_{0}$ is rejected. There is sufficient evidence to indicate female college students score higher than 3.0 on the emotional empathy scale at $\alpha=.01$.
e. The value of $\alpha$ can be just greater than .0011 and we could still reject $H_{0}$.
8.54 a. If chickens are more apt to peck at white string, then they are less apt to peck at blue string. Let $\mu=$ mean number of pecks at a blue string. To determine if chickens are more apt to peck at white string than blue string (or less apt to peck at blue string), we test:
$H_{0}: \mu=7.5$
$H_{\mathrm{a}}: \mu<7.5$

The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{1.13-7.5}{\frac{2.21}{\sqrt{72}}}=-24.46$
The rejection region requires $\alpha=.05$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z<-1.645$.

Since the observed value of the test statistic falls in the rejection region ( $z=-24.46<-1.645$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the chickens are less apt to peck at blue string at $\alpha=.05$.
b. In Exercise 7.21 b, we concluded that the birds were more apt to peck at white string. The mean number of pecks for white string is 7.5 . Since 7.5 is not in the $99 \%$ confidence interval for the mean number of pecks at blue string, it is not a likely value for the true mean for blue string.
c. The $p$-value is $P(z \leq-24.46)=.5-.5 \approx 0$. Since the $p$-value is smaller than $\alpha$ $=0<.05), H_{0}$ is rejected. There is sufficient evidence to indicate the chickens are less apt to peck at blue string at $\alpha=.05$.
8.56
a. $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{52.3-51}{7.1 / \sqrt{50}}=1.29$

$$
\begin{aligned}
p \text {-value } & =P(z \leq-1.29)+P(z \geq 1.29)=(.5-.4015)+(.5-.4015) \\
& =.0985+.0985=.1970
\end{aligned}
$$

b. $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{52.3-51}{7.1 / \sqrt{50}}=1.29$

$$
p \text {-value }=P(z \geq 1.29)=(.5-.4015)=.0985
$$

c. $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{52.3-51}{10.4 / \sqrt{50}}=0.88$

$$
\begin{aligned}
p \text {-value } & =P(z \leq-0.88)+P(z \geq 0.88)=(.5-.3106)+(.5-.3106) \\
& =.1894+.1894=.3788
\end{aligned}
$$

d. For part a, any value of $\alpha$ greater than . 1970 would lead to the rejection of the null hypothesis.

For part b, any value of $\alpha$ greater than .0985 would lead to the rejection of the null hypothesis.

For part $\mathbf{c}$, any value of $\alpha$ greater than . 3788 would lead to the rejection of the null hypothesis.
e. For $p$-value of .01 and a one-tailed test, we need to find a $z$-value so that .01 is to the right of it. From Table IV, Appendix A, $z_{.01}=2.33$.

$$
z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}} \Rightarrow 2.33=\frac{52.3-51}{s / \sqrt{50}} \Rightarrow 2.33 \frac{s}{\sqrt{50}}=1.3 \Rightarrow s=\frac{1.3(\sqrt{50})}{2.33} \Rightarrow s=3.95
$$

For any value of $s$ less than or equal to 3.95 , the $p$-value will be less than or equal to .01 for a one-tailed test.
8.58 We should use the $t$ distribution in testing a hypothesis about a population mean if the sample size is small, the population being sampled from is normal, and the variance of the population is unknown.

$$
\alpha=P(\text { Type I error })=P\left(\text { Reject } H_{0} \text { when } H_{0} \text { is true }\right)
$$

a. $\quad \alpha=P(t>1.440)$ where $\mathrm{df}=6$

$$
=.10 \quad \text { Table VI, Appendix A }
$$

b. $\quad \alpha=P(t<-1.782)$ where $\mathrm{df}=12$

$$
=P(t>1.782)
$$

$$
=.05 \quad \text { Table VI, Appendix A }
$$

c. $\quad \alpha=P(t<-2.060$ or $t>2.060)$ where $\mathrm{df}=25$

$$
\begin{array}{ll}
=2 P(t>2.060) \\
=2(.025) & \\
=.05 & \text { Table VI, Appendix A }
\end{array}
$$

8.62 For this sample,

$$
\begin{array}{ll}
\bar{x}=\frac{\sum x}{n}=\frac{11}{6}=1.8333 \\
s=\sqrt{s^{2}}=2.0412
\end{array}
$$

a. $\quad H_{0}: \mu=3$

$$
H_{\mathrm{a}}: \mu<3
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{1.8333-3}{2.0412 / \sqrt{6}}=-1.40$

The rejection region requires $\alpha=.05$ in the lower tail of the $t$ distribution with $\mathrm{df}=n-1=$ $6-1=5$. From Table VI, Appendix A, $t_{.05}=2.015$. The rejection region is $t<-2.015$.

Since the observed value of the test statistic does not fall in the rejection region $(t=-1.40 \nless-2.015), H_{0}$ is not rejected. There is insufficient evidence to indicate $\mu$ is less than 3 at $\alpha=.05$.
b. $\quad H_{0}: \mu=3$

$$
H_{\mathrm{a}}: \mu \neq 3
$$

Test statistic: $t=-1.40$ (Refer to part a.)
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $t$ distribution with $\mathrm{df}=n-1=6-1=5$. From Table VI, Appendix A, $t_{.025}=2.571$. The rejection region is $t<-2.571$ or $t>2.571$.

Since the observed value of the test statistic does not fall in the rejection region ( $t=-1.40 \nless-2.571$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate $\mu$ differs from 3 at $\alpha=.05$.
c. For part a: $p$-value $=P(t \leq-1.40)$

From Table VI, with $\mathrm{df}=5, P(t \leq-1.40)>.10$.
Using MINITAB, the $p$-value is $p=P(t \leq-1.40)=.110202$.
For part b: $p$-value $=P(t \leq-1.40)+P(t \geq 1.40)$
From Table VI, with df $=5, p$-value $=2 P(t \geq 1.40)>2(.10)=.20$
Using MINITAB, the $p$-value is $p=2 P(t \leq-1.40)=2(.110202)=.220404$.
8.64 a. We must assume that a random sample was drawn from a normal population.
b. The hypotheses are:

$$
\begin{aligned}
& H_{0}: \mu=1000 \\
& H_{\mathrm{a}}: \mu>1000
\end{aligned}
$$

The test statistic is $t=1.89$ and the $p$-value is .038 .
There is evidence to reject $H_{0}$ for $\alpha>.038$. There is evidence to indicate the mean is greater than 1000 for $\alpha>.038$.
c. The hypotheses are:

$$
\begin{aligned}
& H_{0}: \quad \mu=1000 \\
& H_{\mathrm{a}}: \quad \mu \neq 1000
\end{aligned}
$$

The test statistic is $t=1.89$ and the $p$-value is $p=2(.038)=.076$.
There is evidence to reject $H_{0}$ for $\alpha>.076$. There is evidence to indicate the mean is different than 1000 for $\alpha>.076$.
8.66 a. To determine if the average number of books read by all students who participate in the extensive reading program exceeds 25 , we test:

$$
\begin{aligned}
& H_{0}: \mu=25 \\
& H_{\mathrm{a}}: \mu>25
\end{aligned}
$$

b. The rejection region requires $\alpha=.05$ in the upper tail of the $t$ distribution with $\mathrm{df}=n-1$ $=14-1=13$. From Table VI, Appendix A, $t_{.05}=1.771$. The rejection region is $t>1.771$.
c. The test statistic is $t=\frac{\bar{x}-\mu_{0}}{\frac{s}{\sqrt{n}}}=\frac{31.64-25}{\frac{10.49}{\sqrt{14}}}=2.37$
d. Since the observed value of the test statistic falls in the rejection region ( $t=2.37>1.771$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate that the average number of books read by all students who participate in the extensive reading program exceeds 25 at $\alpha=.05$.
e. The conditions required for this test are a random sample from the target population and the population from which the sample is selected is approximately normal.
f. From the printout, the $p$-value is $p=.017$. Since the $p$-value is smaller than $\alpha=.05$ ( $p=.017<.05$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate that the average number of books read by all students who participate in the extensive reading program exceeds 25 at $\alpha=.05$.
8.68 a. The parameter of interest is $\mu=$ mean chromatic contrast of crab-spiders on daisies.
b. To determine if the mean chromatic contrast of crab-spiders on daisies is less than 70, we test:

$$
\begin{aligned}
& H_{0}: \mu=70 \\
& H_{\mathrm{a}}: \mu<70
\end{aligned}
$$

c. $\bar{x}=\frac{\sum x}{n}=\frac{575}{10}=57.5$
$s^{2}=\frac{\sum x^{2}-\frac{\left(\sum x\right)^{2}}{n}}{n-1}=\frac{42,649-\frac{575^{2}}{10}}{10-1}=\frac{9,586.5}{9}=1,065.1667$
$s=\sqrt{1,065.1667}=32.6369$

The test statistic is $t=\frac{\bar{x}-\mu_{o}}{s / \sqrt{n}}=\frac{57.5-70}{\frac{32.6369}{\sqrt{10}}}=-1.21$
d. The rejection region requires $\alpha=.10$ in the lower tail of the $t$-distribution with $d f=n-1=10-1=9$. From Table VI, Appendix A, $t_{.10}=1.383$. The rejection region is $t<-1.383$.
e. Since the observed value of the test statistic does not fall in the rejection region
$(t=-1.21 \nless-1.383), H_{0}$ is not rejected. There is insufficient evidence to indicate that the mean chromatic contrast of crab-spiders on daisies is less than 70 at $\alpha=.10$.
8.70 Let $\mu=$ mean score difference between the first trial and the second trial.
a. To determine if the true mean score difference exceeds 0 , we test:

$$
\begin{aligned}
& H_{0}: \mu=0 \\
& H_{\mathrm{a}}: \quad \mu>0
\end{aligned}
$$

b. The test statistic is $t=\frac{\bar{x}-\mu_{0}}{\frac{s}{\sqrt{n}}}=\frac{.11-0}{\frac{.19}{\sqrt{17}}}=2.387$.

The rejection region requires $\alpha=.05$ in the upper tail of the $t$ distribution, with $\mathrm{df}=$ $n-1=17-1=16$. From Table VI, Appendix A, $\mathrm{t}_{.05}=1.746$. The rejection region is $t$ $>1.746$.

Since the observed value of the test statistic falls in the rejection region $(t=2.387>$ 1.746), $H_{0}$ is rejected. There is sufficient evidence to indicate that the true mean score difference exceeds 0 at $\alpha=.05$.
8.72 Let $\mu=$ mean breaking strength of the new bonding adhesive.

To determine if the mean breaking strength of the new bonding adhesive is less than 5.70 Mpa, we test:
$H_{0}: \mu=5.70$
$H_{\mathrm{a}}: \mu<5.70$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{\frac{s}{\sqrt{n}}}=\frac{5.07-5.70}{\frac{.46}{\sqrt{10}}}=-4.33$.

The rejection region requires $\alpha=.01$ in the lower tail of the t distribution with $\mathrm{df}=n-1$ $=10-1=9$. From Table VI, Appendix A, $t_{.01}=2.821$. The rejection region is $t<-2.821$.

Since the observed value of the test statistic falls in the rejection region
( $t=-4.33<-2.821$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate that the mean breaking strength of the new bonding adhesive is less than 5.70 Mpa at $\alpha=.01$.
8.74 Using MINITAB, the descriptive statistics are:

## Descriptive Statistics: Species

| Variable | N | Mean | StDev | Minimum | Q1 | Median | Q3 | Maximum |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Species | 11 | 12.82 | 18.68 | 3.00 | 4.00 | 5.00 | 7.00 | 52.00 |

To determine if the average number of ant species at Mongolian desert sites differs from 5 species, we test:

$$
\begin{aligned}
& H_{0}: \quad \mu=5 \\
& H_{\mathrm{a}}: \quad \mu \neq 5
\end{aligned}
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{12.82-5}{18.68 / \sqrt{11}}=1.391$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $t$ distribution with $\mathrm{df}=$ $n-1=11-1=10$. From Table VI, Appendix A, $t_{.025}=2.228$. The rejection region is $t<-2.228$ or $t>2.228$.

Since the observed value of the test statistic does not fall in the rejection region $(t=1.391 \ngtr$ 2.228), $H_{0}$ is not rejected. There is insufficient evidence to indicate the average number of ant species at Mongolian desert sites differs from 5 species at $\alpha=.05$.

Using MINITAB, the stem-and-leaf display for the data is:

## Stem-and-Leaf Display: Species

```
Stem-and-leaf of Species N = 11
Leaf Unit = 1.0
    334445557
    2 1
2
2 3
24 9
```

One of the conditions for the above test is that the sample comes from a normal distribution. From the above stem-and-leaf display, the data do not look mound-shaped. This condition is probably not met.
8.76 Some preliminary calculations:

$$
\begin{aligned}
& \bar{x}=\frac{\sum x}{n}=\frac{66}{3}=22 \\
& s^{2}=\frac{\sum x^{2}-\frac{\left(\sum x\right)^{2}}{n}}{n-1}=\frac{1460-\frac{66^{2}}{3}}{3-1}=4 \quad s=\sqrt{4}=2
\end{aligned}
$$

To determine if the mean length of great white sharks off the Bermuda coast exceeds 21 feet, we test:

$$
\begin{aligned}
& H_{0}: \mu=21 \\
& H_{\mathrm{a}}: \mu>21
\end{aligned}
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{22-21}{2 / \sqrt{3}}=0.87$
The rejection region requires $\alpha=.10$ in the upper tail of the $t$ distribution with $\mathrm{df}=n-1=3-$ $1=2$. From Table VI, Appendix A, $t_{10}=1.886$. The rejection region is $z>1.886$.

Since the observed value of the test statistic does not fall in the rejection region ( $t=0.87 \ngtr 1.886$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the mean length of the great white sharks off the Bermuda coast exceeds 21 feet at $\alpha=.10$.
8.78 The conditions required for a valid large-sample test for $p$ are a random sample from a binomial population and a large sample size $n$. The sample size is considered large if both $n p_{o}$ and $n q_{o}$ are at least 15.
8.80 a. Because $\hat{p}=.69$ is less than the hypothesized value of .75 , intuition tells us that this does contradict the null hypothesis that $p=.75$.
b. In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{0}=100(.75)=75$ and $n q_{\mathrm{o}}=100(1-.75)=100(.25)=25$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

$$
\begin{aligned}
& H_{0}: p=.75 \\
& H_{\mathrm{a}}: p<.75
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.69-.75}{\sqrt{\frac{.75(.25)}{100}}}=-1.39$
The rejection region requires $\alpha=.05$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z<-1.645$.

Since the observed value of the test statistic does not fall in the rejection region ( -1.39 $<-1.645), H_{0}$ is not rejected. There is insufficient evidence to indicate that the proportion is less than .75 at $\alpha=.05$.
c. $\quad p$-value $=P(z \leq-1.39)=.5-.4177=.0823$. Since the $p$-value is not less than $\alpha$ ( $p=.0823 \nless .05$ ), $\mathrm{H}_{0}$ is not rejected. There is insufficient evidence to indicate that the proportion is less than . 75 at $\alpha=.05$.
a. $\quad H_{0}: p=.65$

$$
H_{\mathrm{a}}: p>.65
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.74-.65}{\sqrt{\frac{.65(.35)}{100}}}=1.89$

The rejection region requires $\alpha=.01$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{.01}=2.33$. The rejection region is $z>2.33$.

Since the observed value of the test statistic does not fall in the rejection region ( $z=1.89 \ngtr 2.33$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the proportion is greater than . 65 at $\alpha=.01$.
b. $\quad H_{0}: p=.65$

$$
H_{\mathrm{a}}: p>.65
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.74-.65}{\sqrt{\frac{.65(.35)}{100}}}=1.89$
The rejection region requires $\alpha=.10$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{10}=1.28$. The rejection region is $z>1.28$.

Since the observed value of the test statistic falls in the rejection region $(z=1.89>$ 1.28), $H_{0}$ is rejected. There is sufficient evidence to indicate that the proportion is greater than . 65 at $\alpha=.10$.
c. $\quad H_{0}: p=.90$

$$
H_{\mathrm{a}}: p \neq .90
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.74-.90}{\sqrt{\frac{.90(.10)}{100}}}=-5.33$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z .025=1.96$. The rejection region is $z<-1.96$ or $z>1.96$.

Since the observed value of the test statistic falls in the rejection region $(z=-5.33<$ $-1.96), H_{0}$ is rejected. There is sufficient evidence to indicate that the proportion is different from .90 at $\alpha=.05$.
d. For confidence coefficient $.95, \alpha=.05$ and $\alpha / 2=.05 / 2=.025$. From Table IV, Appendix A, $z_{.025}=1.96$. The confidence interval is:

$$
\hat{p} \pm z_{\alpha / 2} \sqrt{\frac{\hat{p} \hat{q}}{n}} \Rightarrow .74 \pm 1.96 \sqrt{\frac{(.74)(.26)}{100}} \Rightarrow .74 \pm .09 \Rightarrow(.65, .83)
$$

e. For confidence coefficient .99, $\alpha=.01$ and $\alpha / 2=.01 / 2=.005$. From Table IV, Appendix A, z.005 $=2.58$. The confidence interval is:

$$
\hat{p} \pm z_{\alpha / 2} \sqrt{\frac{\hat{p} \hat{q}}{n}} \Rightarrow .74 \pm 2.58 \sqrt{\frac{(.74)(.26)}{100}} \Rightarrow .74 \pm .11 \Rightarrow(.63, .85)
$$

8.84 a. Let $p=$ proportion of satellite radio subscribers who have a satellite receiver in their car.
b. To determine if the true proportion of satellite radio subscribers who have satellite radio receivers in their car is too high, we test:

$$
H_{0}: p=.80
$$

c. The alternative hypothesis would be:

$$
H_{a}: p<.80
$$

d. The sample proportion is $\hat{p}=\frac{396}{501}=.79$. The test statistic is:

$$
z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.79-.80}{\sqrt{\frac{.8(1-.8)}{501}}}=-.56
$$

e. The rejection region requires $\alpha=.10$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{10}=1.28$. The rejection region is $z<-1.28$.
f. The $p$-value is $p=P(z \leq-.56)=P(z \geq .56)=(.5-.2123)=.2877$. (From Table IV, Appendix A.)
g. Since the $p$-value is greater than $\alpha=.10(p=.2877>.10), H_{0}$ is not rejected. There is insufficient evidence to indicate the true proportion of satellite radio subscribers who have satellite radio receivers in their car is less than . 80 at $\alpha=.10$.

Since the observed value of the test statistic does not fall in the rejection region $(z=-.56$ $\$-1.28), H_{0}$ is not rejected. There is insufficient evidence to indicate the true proportion of satellite radio subscribers who have satellite radio receivers in their car is less than .80 at $\alpha=.10$.
8.86 a. Let $p=$ true proportion of students who correctly identify the color. If there is no relationship between color and flavor, then $p=.5$.
b. To determine if color and flavor are related, we test:

$$
\begin{aligned}
& H_{0}: \quad p=.5 \\
& H_{\mathrm{a}}: \quad p \neq .5
\end{aligned}
$$

c. In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{0}=121(.5)=60.5$ and $n q_{0}=121(1-.5)=121(.5)=60.5$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

The sample proportion is $\hat{p}=\frac{97}{121}=.80$. The test statistic is:

$$
z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.80-.5}{\sqrt{\frac{.5(1-.5)}{121}}}=6.60
$$

The $p$-value is $p=P(z \geq 6.60)+P(z \leq-6.60) \approx(.5-.5)+(.5-.5)=0$. Since the $p$ value is less than $\alpha(p=0<.01), H_{0}$ is rejected. There is sufficient evidence to indicate color and flavor are related at $\alpha=.01$.
8.88 Let $p=$ true proportion of all U.S. teenagers who have used at least one informal element in school writing assignments.

The sample proportion is $\hat{p}=\frac{448}{700}=.64$.
In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{\mathrm{o}}=700(.65)=455$ and $n q_{\mathrm{o}}=700(1-.65)=700(.35)=245$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if less than $65 \%$ of all U.S. teenagers have used at least one informal element in school writing assignments, we test:

$$
\begin{array}{ll}
H_{0}: & p=.65 \\
H_{\mathrm{a}}: & p<.65
\end{array}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sigma_{\hat{p}}}=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.64-.65}{\sqrt{\frac{.65(1-.65)}{700}}}=-.55$
The rejection region requires $\alpha=.05$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z<-1.645$.

Since the observed value of the test statistic does not fall in the rejection region ( $z=-.55 \nless-1.645$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that less than $65 \%$ of all U.S. teenagers have used at least one informal element in school writing assignments at $\alpha=.05$.
8.90 a. $\hat{p}=\frac{x}{n}=\frac{315}{500}=.63$

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{\mathrm{o}}=500(.60)=300$ and $n q_{\mathrm{o}}=500(1-.60)=500(.40)=200$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if the GSR for all scholarship athletes at Division I institutions differs from $60 \%$, we test:

$$
\begin{aligned}
& H_{0}: p=.60 \\
& H_{\mathrm{a}}: p \neq .60
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{o}}{\sqrt{\frac{p_{o} q_{o}}{n}}}=\frac{.63-.60}{\sqrt{\frac{.60(.40)}{500}}}=1.37$
The rejection region requires $\alpha / 2=.01 / 2=.005$ in each tail of the $z$-distribution. From Table IV, Appendix A, $z .005=2.58$. The rejection region is $z>2.58$ or $z<-2.58$.

Since the observed value of the test statistic does not fall in the rejection region $(z=1.37 \ngtr 2.58), H_{0}$ is not rejected. There is insufficient evidence to indicate the GSR for all scholarship athletes at Division I institutions differs from $60 \%$ at $\alpha=.01$.
b. $\quad \hat{p}=\frac{x}{n}=\frac{84}{200}=.42$

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{0}=200(.58)=116$ and $n q_{0}=200(1-.58)=200(.42)=84$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if the GSR for all male basketball players at Division I institutions differs from $58 \%$, we test:
$H_{0}: p=.58$
$H_{\mathrm{a}}: p \neq .58$

The test statistic is $z=\frac{\hat{p}-p_{o}}{\sqrt{\frac{p_{o} q_{o}}{n}}}=\frac{.42-.58}{\sqrt{\frac{.58(.42)}{200}}}=-4.58$
The rejection region requires $\alpha / 2=.01 / 2=.005$ in each tail of the $z$-distribution. From Table IV, Appendix A, $z .005=2.58$. The rejection region is $z>2.58$ or $z<-2.58$.

Since the observed value of the test statistic falls in the rejection region ( $z=-4.58<-2.58$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the GSR for all male basketball players at Division I institutions differs from $58 \%$ at $\alpha=.01$.

### 8.92 For the Top of the Core:

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{0}=84(.50)=42$ and $n q_{0}=84(1-.50)=84(.50)=42$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

$$
\hat{p}=\frac{x}{n}=\frac{64}{84}=.762
$$

To determine if the coat index exceeds .5 , we test:

$$
\begin{aligned}
& H_{0}: p=.5 \\
& H_{\mathrm{a}}: p>.5
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.762-.5}{\sqrt{\frac{.5(.5)}{84}}}=4.80$
The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z .05=1.645$. The rejection region is $z>1.645$.

Since the observed value of the test statistic falls in the rejection region $(z=4.80>1.645), H_{0}$ is rejected. There is sufficient evidence to indicate that the coat index exceeds . 5 at $\alpha=.05$.

## For the Middle of the Core:

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{\mathrm{o}}$ and $n q_{\mathrm{o}}$ are greater than or equal to 15 .
$n p_{0}=73(.50)=36.5$ and $n q_{0}=73(1-.50)=73(.50)=36.5$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

$$
\hat{p}=\frac{x}{n}=\frac{35}{73}=.479
$$

To determine if the coat index differs from .5 , we test:
$H_{0}: p=.5$
$H_{\mathrm{a}}: p \neq .5$
The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.479-.5}{\sqrt{\frac{.5(.5)}{73}}}=-.36$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z .025=1.96$. The rejection region is $z<-1.96$ or $z>1.96$.

Since the observed value of the test statistic does not fall in the rejection region ( $z=-.36 \nless-1.96$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the coat index differs from . 5 at $\alpha=.05$.

## For the Bottom of the Core:

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{\mathrm{o}}$ and $n q_{\mathrm{o}}$ are greater than or equal to 15 .
$n p_{0}=81(.50)=40.5$ and $n q_{0}=81(1-.50)=81(.50)=40.5$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

$$
\hat{p}=\frac{x}{n}=\frac{29}{81}=.358
$$

To determine if the coat index is less than .5 , we test:

$$
\begin{aligned}
& H_{0}: p=.5 \\
& H_{\mathrm{a}}: p<.5
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.358-.5}{\sqrt{\frac{.5(.5)}{81}}}=-2.56$
The rejection region requires $\alpha=.05$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z<-1.645$.

Since the observed value of the test statistic falls in the rejection region ( $z=-2.56<-1.645$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate that the coat index is less than .5 at $\alpha=.05$.
8.94 Let $p=$ true mortality rate for weevils exposed to nitrogen.

The point estimate for the population parameter is

$$
\hat{p}=\frac{x}{n}=\frac{31,386}{31,386+35}=\frac{31,386}{31,421}=.9989 .
$$

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{\mathrm{o}}$ and $n q_{\mathrm{o}}$ are greater than or equal to 15 .
$n p_{\mathrm{o}}=31,421(.99)=31,106.79$ and $n q_{0}=31,421(1-.99)=31,421(.01)=314.21$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if the true mortality rate for weevils exposed to nitrogen is higher than $99 \%$, we test:

$$
\begin{array}{ll}
H_{0}: & p=.99 \\
H_{\mathrm{a}}: & p>.99
\end{array}
$$

The test statistic is $z=\frac{\hat{p}-p_{o}}{\sqrt{\frac{p_{o} q_{o}}{n}}}=\frac{.9989-.99}{\sqrt{\frac{.99(.01)}{31,421}}}=15.86$
The $p$-value for the test is $p=P(z \geq 15.86) \approx .5-.5=0$. (From Table IV, Appendix A.) Since the $p$-value is so small, we would reject $H_{0}$ for any reasonable value of $\alpha$. There is sufficient evidence to indicate the true mortality rate for weevils exposed to nitrogen is higher than 99\%.

From the study, the entomologists could conclude that the mortality rate for nitrogen after 24 hours is higher than that for carbon dioxide after 4 days.
8.96 The power of a test is the probability that the test will correctly lead to the rejection of the null hypothesis for a particular value of $\mu$ in the alternative hypothesis. The power is equal to ( $1-\beta$ ) for the particular alternative considered.
8.98 Three factors that will increase the power of a test are:

1. Increase the value of $\alpha$ (as $\alpha$ increases, $\beta$ decreases which causes the power to increase).
2. Increase the sample size (as $n$ increases, $\beta$ decreases).
3. Increase the distance between $\mu_{0}$ and $\mu_{\mathrm{a}}$.
8.100 a. From Exercise 8.99, we want to find $\bar{x}_{0}$ such that

$$
\begin{aligned}
& P\left(\bar{x}>\bar{x}_{0}\right)=.05 \\
& P\left(\bar{x}>\bar{x}_{0}\right)=P\left(z>\frac{\bar{x}_{0}-1000}{120 / \sqrt{36}}\right)=P\left(z>\frac{\bar{x}_{0}-1000}{20}\right)=.05
\end{aligned}
$$

$P\left(z>z_{0}\right)=.05 \Rightarrow$ We want to find $z_{0}$ such that .05 of the area is to the right of it and $.5-.05=.4500$ of the area is between 0 and $z_{0}$. From Table IV, Appendix A, $z_{0}=1.645$.

$$
z_{0}=\frac{\bar{x}_{0}-100}{20} \Rightarrow 1.645=\frac{\bar{x}-1000}{20} \Rightarrow \bar{x}_{0}=1032.9
$$

If $\mu=1040$,

$$
\beta=P(\bar{x}<1032.9)=P\left(z<\frac{1032.9-1040}{120 / \sqrt{36}}\right)=P(z<-.36)=.5-.1406=.3594
$$

b. Power $=1-\beta=1-.3594=.6406$
c. From Exercise $8.99, \beta=.7422$ and the power is .2578 .

The value of $\beta$ when $\mu=1040$ is .3594 as compared with .7422 when $\mu=1020$. Thus, the probability of accepting $H_{0}$ when it is false when $\mu=1040$ is smaller than when $\mu=1020$.

The power when $\mu=1040$ is . 6406 as compared with .2578 when $\mu=1020$. Thus, the probability of rejecting $H_{0}$ when it is false is larger when $\mu=1040$ than when $\mu=1020$.
8.102 a. From Exercise 8.101, we know $\mu_{\bar{x}}=\mu=50$ and $\sigma_{\bar{x}}=\sigma / \sqrt{n}=20 / \sqrt{64}=2.5$

The rejection region requires $\alpha=.10$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{10}=1.28$. The rejection region is $z<-1.28$.

$$
z_{0}=\frac{\bar{x}_{0}-\mu_{0}}{\sigma_{\bar{x}}} \Rightarrow-1.28=\frac{\bar{x}_{0}-50}{2.5} \Rightarrow \bar{x}_{0}=46.8
$$

For $\mu=49, \beta=P(\bar{x}>46.8)=P\left(z>\frac{46.8-49}{2.5}\right)=P(z>-.88)=.5+.3106=.8106$
(from Table IV, Appendix A)

For $\mu=47, \beta=P(\bar{x}>46.8)=P\left(z>\frac{46.8-47}{2.5}\right)=P(z>-.08)=.5+.0319=.5319$
For $\mu=45, \beta=P(\bar{x}>46.8)=P\left(z>\frac{46.8-45}{2.5}\right)=P(z>.72)=.5-.2642=.2358$
For $\mu=43, \beta=P(\bar{x}>46.8)=P\left(z>\frac{46.8-43}{2.5}\right)=P(z>1.52)=.5-.4357=.0643$
For $\mu=41, \beta=P(\bar{x}>46.8)=P\left(z>\frac{46.8-41}{2.5}\right)=P(z>2.32)=.5-.4898=.0102$
b.

c. From the graph, when $\mu=48, \beta \approx .67$.
d. For $\mu=49$, Power $=1-\beta=1-.8106=.1894$

For $\mu=47$, Power $=1-\beta=1-.5319=.4681$
For $\mu=45$, Power $=1-\beta=1-.2358=.7642$
For $\mu=43$, Power $=1-\beta=1-.0643=.9357$
For $\mu=41$, Power $=1-\beta=1-.0102=.9898$

The power decreases as $\mu$ increases, while the value of $\beta$ increases as $\mu$ increases (or gets closer to $\mu=50$ ).
e. The further $\mu$ is from $\mu_{0}=50$, the larger the power and the smaller the value of $\beta$. This indicates the probability of rejecting $H_{0}$ when $\mu$ gets further from $\mu_{0}$ (power)
increases. The probability of accepting $H_{0}$ when $\mu$ gets further from $\mu_{0}(\beta)$ decreases.
The further $\mu$ gets from $\mu_{0}$, the smaller the chances of making an incorrect decision.
8.104 a. First, we find $\bar{x}_{o}$ such that $P\left(\bar{x}<\bar{x}_{o}\right)=.01$.

From Exercise 8.28, we know that $z_{o}=-2.33$. Thus,

$$
\begin{aligned}
& z_{o}=\frac{\bar{x}_{o}-\mu_{o}}{\frac{\sigma}{\sqrt{n}}}=\frac{\bar{x}_{o}-20}{\frac{11.9}{\sqrt{46}}}=\frac{\bar{x}_{o}-20}{1.7546}=-2.33 \\
& \Rightarrow \bar{x}_{o}=-2.33(1.7546)+20=15.912 \\
& \text { Power }=P(\bar{x}<15.912 \text { when } \mu=19)=P\left(z<\frac{15.912-19}{1.7546}\right) \\
& \quad=P(z<-1.76)=.5-.4608=.0392
\end{aligned}
$$

b. For $\mu=18$,

$$
\begin{aligned}
\text { Power } & =P(\bar{x}<15.912 \text { when } \mu=18)=P\left(z<\frac{15.912-18}{1.7546}\right) \\
& =P(z<-1.19)=.5-.3830=.1170
\end{aligned}
$$

For $\mu=16$,

$$
\begin{aligned}
\text { Power } & =P(\bar{x}<15.912 \text { when } \mu=16)=P\left(z<\frac{15.912-16}{1.7546}\right) \\
& =P(z<-0.05)=.5-.0199=.4801
\end{aligned}
$$

For $\mu=14$,

$$
\begin{aligned}
\text { Power } & =P(\bar{x}<15.912 \text { when } \mu=14)=P\left(z<\frac{15.912-14}{1.7546}\right) \\
& =P(z<1.09)=.5+.3621=.8621
\end{aligned}
$$

For $\mu=12$,

$$
\begin{aligned}
\text { Power } & =P(\bar{x}<15.912 \text { when } \mu=12)=P\left(z<\frac{15.912-12}{1.7546}\right) \\
& =P(z<2.23)=.5+.4871=.9871
\end{aligned}
$$

c. Using MINITAB, the plot is:

As the mean gets further away from 20, the power increases.
d. For $\mu=15$, we would estimate the power to be about .7.

$$
\begin{aligned}
\text { Power } & =P(\bar{x}<15.912 \text { when } \mu=15)=P\left(z<\frac{15.912-15}{1.7546}\right) \\
& =P(z<0.52)=.5+.1985=.6985
\end{aligned}
$$

e. The probability that the test will fail to reject $H_{0}$ is $\beta=1-$ Power $=1-.6985=.3015$.
8.106 a. To determine if the mean mpg for 2009 Honda Civic autos is greater than 36 mpg , we test:

$$
\begin{aligned}
& H_{0}: \mu=36 \\
& H_{\mathrm{a}}: \mu>36
\end{aligned}
$$

b. The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{38.3-36}{6.4 / \sqrt{50}}=2.54$

The rejection region requires $\alpha=.05$ in the upper tail of the $z$-distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z>1.645$.

Since the observed value of the test statistic falls in the rejection region $(z=2.54>$ $1.645), H_{0}$ is rejected. There is sufficient evidence to indicate that the mean mpg for 2009 Honda Civic autos is greater than 36 mpg at $\alpha=.05$.

We must assume that the sample was a random sample.
c. First, we find $\bar{x}_{o}$ such that $P\left(\bar{x}>\bar{x}_{o}\right)=.05$.

From part b, we know that $z_{o}=1.645$. Thus,
$z_{o}=\frac{\bar{x}_{o}-\mu_{o}}{\frac{\sigma}{\sqrt{n}}}=\frac{\bar{x}_{o}-36}{\frac{6.4}{\sqrt{50}}}=\frac{\bar{x}_{o}-36}{.9051}=1.645$
$\Rightarrow \bar{x}_{o}=1.645(.9051)+36=37.49$

For $\mu=36.5$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=36.5)=P\left(z>\frac{37.49-36.5}{.9051}\right) \\
& =P(z>1.09)=.5-.3621=.1379
\end{aligned}
$$

For $\mu=37$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=37)=P\left(z>\frac{37.49-37}{.9051}\right) \\
& =P(z>.54)=.5-.2054=.2946
\end{aligned}
$$

For $\mu=37.5$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=37.5)=P\left(z>\frac{37.49-37.5}{.9051}\right) \\
& =P(z>-.01)=.5+.0040=.5040
\end{aligned}
$$

For $\mu=38$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=38)=P\left(z>\frac{37.49-38}{.9051}\right) \\
& =P(z>-.56)=.5+.2123=.7123
\end{aligned}
$$

For $\mu=38.5$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=38.5)=P\left(z>\frac{37.49-38.5}{.9051}\right) \\
& =P(z>-1.12)=.5+.3686=.8686
\end{aligned}
$$

d. Using MINITAB, the plot is:

e. From the plot, the power is approximately .6.

For $\mu=37.75$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=37.75)=P\left(z>\frac{37.49-37.75}{.9051}\right) \\
& =P(z>-.29)=.5+.1141=.6141
\end{aligned}
$$

f. From the plot, the power is approximately 1.

For $\mu=41$ :

$$
\begin{aligned}
\text { Power } & =P(\bar{x}>37.49 \text { when } \mu=41)=P\left(z>\frac{37.49-41}{.9051}\right) \\
& =P(z>-3.88) \approx .5+.5=1
\end{aligned}
$$

If the true value of $\mu$ is 41 , the approximate probability that the test will fail to reject $H_{0}$ is $1-1=0$.
8.108 First, we find $\hat{p}_{o}$ such that $P\left(\hat{p}<\hat{p}_{o}\right)=.10$.

From Exercise 8.84, we know that $z_{o}=-1.28$. Thus,

$$
\begin{aligned}
& z_{o}=\frac{\hat{p}_{o}-p_{o}}{\sqrt{\frac{p_{o} q_{o}}{n}}}=\frac{\hat{p}_{o}-.80}{\sqrt{\frac{.80(.20)}{501}}}=\frac{\hat{p}_{o}-.80}{.01787}=-1.28 \\
& \Rightarrow \hat{p}_{o}=-1.28(.01787)+.80=.777
\end{aligned}
$$

$$
\text { Probability }=P\left(\hat{p}_{o}<.777 \text { when } p=.82\right)=P\left(z<\frac{.777-.82}{\sqrt{\frac{.82(.18)}{501}}}\right)
$$

$$
=P(z<-2.51)=.5-.4940=.0060
$$

8.110 The sampling distribution used for making inferences about $\sigma^{2}$ is the chi-squared distribution.
8.112 The statement "The null hypotheses, $H_{0}: \sigma^{2}=25$ and $H_{0}: \sigma=5$, are equivalent" is true. We know that the standard deviation $(\sigma)$ can only be the positive square root of the variance ( $\sigma^{2}$ ).
8.114 Using Table VII, Appendix A:
a. For $n=12, \mathrm{df}=n-1=12-1=11$

$$
P\left(\chi^{2}>\chi_{0}^{2}\right)=.10 \Rightarrow \chi_{0}^{2}=17.2750
$$

b. For $n=9, \mathrm{df}=n-1=9-1=8$

$$
P\left(\chi^{2}>\chi_{0}^{2}\right)=.05 \Rightarrow \chi_{0}^{2}=15.5073
$$

c. For $n=5, \mathrm{df}=n-1=5-1=4$

$$
P\left(\chi^{2}>\chi_{0}^{2}\right)=.025 \Rightarrow \chi_{0}^{2}=11.1433
$$

8.116 a. It would be necessary to assume that the population has a normal distribution.
b. $\quad H_{0}: \sigma^{2}=1$

$$
H_{\mathrm{a}}: \sigma^{2}>1
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{(7-1)(1.84)}{1}=11.04$
The rejection region requires $\alpha=.05$ in the upper tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1=7-1=6$. From Table VII, Appendix A, $\chi_{.05}^{2}=12.5916$. The rejection region is $\chi^{2}>12.5916$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=11.04 \ngtr 12.5916$ ), $H_{0}$ not is rejected. There is insufficient evidence to indicate that the variance is greater than 1 at $\alpha=.05$.
c. Using Table VII, with $\mathrm{df}=n-1=7-1=6$, the $p$-value would be

$$
p=P\left(\chi^{2} \geq 14.45\right)=.025
$$

d. $\quad H_{0}: \sigma^{2}=1$

$$
H_{\mathrm{a}}: \quad \sigma^{2} \neq 1
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{(7-1) 1.84}{1}=11.04$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1=7-1=6$. From Table VII, Appendix A, $\chi_{975}^{2}=1.237347$ and $\chi_{.025}^{2}=14.4494$. The rejection region is $\chi^{2}<1.237347$ or $\chi^{2}>14.4494$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=11.04 \ngtr 14.4494$ and $\chi^{2}=11.04 \nless 1.237347$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the variance is not equal to 1 at $\alpha=.05$.
8.118 Some preliminary calculations are:

$$
s^{2}=\frac{\sum x^{2}-\frac{\left(\sum x\right)^{2}}{n}}{n-1}=\frac{176-\frac{30^{2}}{7}}{7-1}=7.9048
$$

To determine if $\sigma^{2}<2$, we test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=2 \\
& H_{\mathrm{a}}: \sigma^{2}<2
\end{aligned}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{(7-1) 7.9048}{2}=23.71$
The rejection region requires $\alpha=.05$ in the lower tail of the $\chi^{2}$ distribution with df $=n-1=7-1=6$. From Table VII, Appendix A, $\chi_{95}^{2}<1.63539$. The rejection region is $\chi^{2}<1.63539$.

Since the observed value of the test statistic does not fall in the rejection region $\left(\chi^{2}=23.71 \nless 1.63539\right), H_{0}$ is not rejected. There is insufficient evidence to indicate the variance is less than 1 at $\alpha=.05$.
8.120 a . To determine if the breaking strength variance differs from .5 Mpa , We test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=.5 \\
& H_{\mathrm{a}}: \sigma^{2} \neq .5
\end{aligned}
$$

b. The rejection region requires $\alpha / 2=.01 / 2=.005$ in the upper tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1=10-1=9$. From Table VII, Appendix A, $\chi_{995}^{2}=1.734926$ and $\chi_{.005}^{2}=23.5893$. The rejection region is $\chi^{2}<1.734926$ or $\chi^{2}>25.5893$.
c. The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma^{2}}=\frac{(10-1)(.46)^{2}}{.5}=3.809$.
d. Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=3.809 \nless 1.734926$ and $\chi^{2}=3.809 \ngtr 25.5893$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the breaking strength variance differs from . 5 Mpa at $\alpha=$. 01 .
e. The conditions required for the test results to be valid are:

1. A random sample is selected from the target population.
2. The population from which the sample is selected has a distribution that is approximately normal.
8.122 a. If the standard deviation is less than 22 , then the variance is less than $22^{2}=484$. To determine if the standard deviation of all grassland pixels is less than 22, we test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=484 \\
& H_{\mathrm{a}}: \sigma^{2}<484
\end{aligned}
$$

b. The $p$-value of the test is $p=.105$. Since the $p$-value is not less than $\alpha=.10$ ( $p=.105 \nless .10$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the standard deviation of all grassland pixels is less than 22 at $\alpha=.10$.
8.124 Using MINITAB, the descriptive statistics are:

## Descriptive Statistics: Species

| Variable | N | Mean | StDev | Minimum | Q1 | Median | Q3 | Maximum |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Species | 11 | 12.82 | 18.68 | 3.00 | 4.00 | 5.00 | 7.00 | 52.00 |

To determine if the standard deviation of the number of species at all Mongolian desert sites exceeds 15 species (variance exceeds $15^{2}=225$ ), we test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=225 \\
& H_{\mathrm{a}}: \sigma^{2}>225
\end{aligned}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma^{2}}=\frac{(11-1)\left(18.68^{2}\right)}{225}=15.51$.
The rejection region requires $\alpha=.05$ in the upper tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1$ $=11-1=10$. From Table VII, Appendix A, $\chi_{.05}^{2}=18.3070$. The rejection region is $\chi^{2}>18.3070$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=15.51 \ngtr 18.3070$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the standard deviation of the number of species at all Mongolian desert sites exceeds 15 species (variance exceeds $15^{2}=225$ ) at $\alpha=.05$.

The conditions required for the test results to be valid are:

1. A random sample is selected from the target population.
2. The population from which the sample is selected has a distribution that is approximately normal.

A stem-and-leaf display of the data is:

## Stem-and-Leaf Display: Species

```
Stem-and-leaf of Species N = 11
Leaf Unit = 1.0
    334445557
2 1
2
2 3
24 9
1 5 2
```

The condition that the data come from a normal distribution does not appear to be met.
8.126 From Exercise 8.34, $s=1,595$. To determine if the heat rates of the augmented gas turbine engine are more variable than the heat rates of the standard gas turbine engine, we test:

$$
\begin{array}{ll}
H_{0}: & \sigma^{2}=1,500^{2}=2,250,000 \\
H_{\mathrm{a}}: & \sigma^{2}>2,250,000
\end{array}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{o}^{2}}=\frac{(67-1) 1,595^{2}}{1,500^{2}}=74.6247$
The rejection region requires $\alpha=.05$ in the upper tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1=67-1=66$. From Table VII, Appendix A, $\chi_{.05}^{2} \approx 79.0819$. The rejection region is $\chi^{2}>79.0819$.

Since the observed value of the test statistic does not fall in the rejection region $\chi^{2}=74.6247 \ngtr 79.0819$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate the heat rates of the augmented gas turbine engine are more variable than the heat rates of the standard gas turbine engine at $\alpha=.05$.
8.128 The psychologist claims that the range of WR scores is 42 . If the WR scores are normally distributed, then approximately $95 \%$ of the scores fall within 2 standard deviations of the mean and approximately $99.7 \%$ of the scores fall within 3 standard deviations of the mean. Thus, the range will cover between 4 and 6 standard deviations. We will use the 6 standard deviations. The estimate of the standard deviation is the range divided by 6 or $42 / 6=7$. To determine if the psychologists claim is correct, we test:

$$
\begin{array}{ll}
H_{0}: & \sigma^{2}=7^{2}=49 \\
H_{a}: & \sigma^{2} \neq 49
\end{array}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{o}^{2}}=\frac{(100-1) 6^{2}}{7^{2}}=72.735$
Since no $\alpha$ is given, we will use $\alpha=.05$. The rejection region requires $\alpha / 2=.05 / 2=.025$ in the each tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1=100-1=99$. From Table VII, Appendix A, $\chi_{.975}^{2} \approx 74.2219$ and $\chi_{.025}^{2} \approx 129.561$. The rejection region is $\chi^{2}<74.2219$ or $\chi^{2}>129.561$.

Since the observed value of the test statistic falls in the rejection region ( $\chi^{2}=72.735<74.2219$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the psychologist's claim is incorrect at $\alpha=.05$.
8.130 For a large sample test of hypothesis about a population mean, no assumptions are necessary because the Central Limit Theorem assures that the test statistic will be approximately normally distributed. For a small sample test of hypothesis about a population mean, we must assume that the population being sampled from is normal. For both the large and small sample tests we must assume that we have a random sample. The test statistic for the large sample test is the $z$ statistic, and the test statistic for the small sample test is the $t$ statistic.
$8.132 \alpha=P($ Type I error $)=P\left(\right.$ rejecting $H_{0}$ when it is true $)$. Thus, if rejection of $H_{0}$ would cause your firm to go out of business, you would want this probability to be small.
8.134 a. For confidence coefficient .90, $\alpha=.10$ and $\alpha / 2=.05$. From Table VI, Appendix A, with $\mathrm{df}=n-1=20-1=19, t_{.05}=1.729$. The confidence interval is:

$$
\bar{x} \pm t_{\alpha / 2} \frac{s}{\sqrt{n}} \Rightarrow 72.6 \pm 1.729 \frac{\sqrt{19.4}}{\sqrt{20}} \Rightarrow 72.6 \pm 1.70 \Rightarrow(70.90,74.30)
$$

b. $\quad H_{0}: \mu=80$

$$
H_{\mathrm{a}}: \mu<80
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{72.6-80}{\sqrt{19.4} / \sqrt{20}}=-7.51$
The rejection region requires $\alpha=.05$ in the lower tail of the $t$ distribution with $\mathrm{df}=n-1$ $=20-1=19$. From Table VI, Appendix A, $t_{.05}=1.729$. The rejection region is $t<-1.729$.

Since the observed value of the test statistic falls in the rejection region $(t=-7.51<$ $-1.729), H_{0}$ is rejected. There is sufficient evidence to indicate that the mean is less than 80 at $\alpha=.05$.
c. $\quad H_{0}: \mu=80$

$$
H_{\mathrm{a}}: \mu \neq 80
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{72.6-80}{\sqrt{19.4} / \sqrt{20}}=-7.51$

The rejection region requires $\alpha / 2=.01 / 2=.005$ in each tail of the $t$ distribution with df $=n-1=20-1=19$. From Table VI, Appendix A, $t_{.005}=2.861$. The rejection region is $t<-2.861$ or $t>2.861$.

Since the observed value of the test statistic falls in the rejection region $(t=-7.51<$ $-2.861), H_{0}$ is rejected. There is sufficient evidence to indicate that the mean is different from 80 at $\alpha=.01$.
d. For confidence coefficient $.99, \alpha=.01$ and $\alpha / 2=.01 / 2=.005$. From Table VI, Appendix A, with df $=n-1=20-1=19, t_{.005}=2.861$. The confidence interval is:

$$
\bar{x} \pm t_{\alpha / 2} \frac{s}{\sqrt{n}} \Rightarrow 72.6 \pm 2.861 \frac{\sqrt{19.4}}{\sqrt{20}} \Rightarrow 72.6 \pm 2.82 \Rightarrow(69.78,75.42)
$$

e. $n=\frac{\left(z_{\alpha / 2}\right) \sigma^{2}}{B^{2}} \approx \frac{(1.96)^{2}(19.4)}{1^{2}}=74.53 \approx 75$
8.136 a. For confidence coefficient $.95, \alpha=.05$ and $\alpha / 2=.05 / 2=.025$. From Table IV, Appendix A, $z_{.025}=1.96$. The confidence interval is:

$$
\bar{x} \pm z_{\alpha / 2} \frac{\sigma}{\sqrt{n}} \Rightarrow 8.2 \pm 1.96 \frac{.79}{\sqrt{175}} \Rightarrow 8.2 \pm .12 \Rightarrow(8.08,8.32)
$$

We are $95 \%$ confident the mean is between 8.08 and 8.32 .
b. $\quad H_{0}: \mu=8.3$
$H_{\mathrm{a}}: \mu \neq 8.3$
The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{8.2-8.3}{.79 / \sqrt{175}}=-1.67$

The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z_{.025}=1.96$. The rejection region is $z<-1.96$ or $z>1.96$.

Since the observed value of the test statistic does not fall in the rejection region $(z=$ $-1.67 \nless-1.96), H_{0}$ is not rejected. There is insufficient evidence to indicate that the mean is different from 8.3 at $\alpha=.05$.
c. $\quad H_{0}: \mu=8.4$
$H_{\mathrm{a}}: \mu \neq 8.4$
The test statistic is $z=\frac{\bar{x}-\mu_{0}}{\sigma_{\bar{x}}}=\frac{8.2-8.4}{.79 / \sqrt{175}}=-3.35$

The rejection region is the same as part $\mathbf{b}, z<-1.96$ or $z>1.96$.
Since the observed value of the test statistic falls in the rejection region $(z=-3.35<$ $-1.96), H_{0}$ is rejected. There is sufficient evidence to indicate that the mean is different from 8.4 at $\alpha=.05$.
8.138 a. The $p$-value $=.1288=P(t \geq 1.174)$. Since the $p$-value is not very small, there is no evidence to reject $H_{0}$ for $\alpha \leq .10$. There is no evidence to indicate the mean is greater than 10 .
b. We must assume that we have a random sample from a population that is normally distributed.
c. For the alternative hypothesis $H_{\mathrm{a}}: \mu \neq 10$, the $p$-value is 2 times the $p$-value for the onetailed test. The $p$-value $=2(.1288)=.2576$. There is no evidence to reject $H_{0}$ for $\alpha \leq .10$. There is no evidence to indicate the mean is different from 10 .
8.140 a. Since the company must give proof the drug is safe, the null hypothesis would be the drug is unsafe. The alternative hypothesis would be the drug is safe.
b. A Type I error would be concluding the drug is safe when it is not safe. A Type II error would be concluding the drug is not safe when it is. $\alpha$ is the probability of concluding the drug is safe when it is not. $\beta$ is the probability of concluding the drug is not safe when it is.
c. In this problem, it would be more important for $\alpha$ to be small. We would want the probability of concluding the drug is safe when it is not to be as small as possible.
8.142 a. The point estimate for $p$ is $\hat{p}=\frac{x}{n}=\frac{35}{1,165}=.030$

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{\mathrm{o}}$ and $n q_{\mathrm{o}}$ are greater than or equal to 15 .
$n p_{\mathrm{o}}=1,165(.02)=23.3$ and $n q_{\mathrm{o}}=1,165(1-.02)=1,165(.98)=1,141.7$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if the true driver cell phone use rate differs from .02 , we test:
$H_{0}: p=.02$
$H_{\mathrm{a}}: p \neq .02$
The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.030-.02}{\sqrt{\frac{.02(.98)}{1,165}}}=2.44$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the z distribution. From Table IV, Appendix A, $z_{.025}=1.96$. The rejection region is $z<-1.96$ or $z>1.96$.

Since the observed value of the test statistic falls in the rejection region ( $z=2.44>1.96$ ), $H_{0}$ is rejected. There is sufficient evidence to indicate the true driver cell phone use rate differs from . 02 at $\alpha=.05$.
b. In Exercise 7.119, the confidence interval for $p$ is (.020, .040). Since .02 is contained in this interval, there is no evidence to reject $H_{0}$. This does not agree with the conclusion for this test. However, if the calculations were carried out to 4 decimal places, the interval would be (.0202, .0398). Using this interval, .02 is not contained in the interval. This agrees with the test in part a.
8.144 In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{o}$ and $n q_{o}$ are greater than or equal to 15 .
$n p_{0}=100(.5)=50$ and $n q_{0}=100(1-.5)=100(.5)=50$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

$$
\hat{p}=\frac{x}{n}=\frac{56}{100}=.56
$$

To determine if more than half of all Diet Coke drinkers prefer Diet Pepsi, we test:

$$
\begin{aligned}
& H_{0}: p=.5 \\
& H_{\mathrm{a}}: p>.5
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.56-.5}{\sqrt{\frac{.5(.5)}{100}}}=1.20$
The rejection region requires $\alpha=.05$ in the upper tail of the $z$ distribution. From Table IV, Appendix A, $z_{.05}=1.645$. The rejection region is $z>1.645$.

Since the observed value of the test statistic does not fall in the rejection region $(z=1.20 \ngtr$ 1.645), $H_{0}$ is not rejected. There is insufficient evidence to indicate that more than half of all Diet Coke drinkers prefer Diet Pepsi at $\alpha=.05$.

Since $H_{0}$ was not rejected, there is no evidence that Diet Coke drinkers prefer Diet Pepsi.
8.146 To determine if the variance of the solution times differs from 2 , we test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=2 \\
& H_{\mathrm{a}}: \sigma^{2} \neq 2
\end{aligned}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{(52-1) 2.2643}{2}=57.74$
The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $\chi^{2}$ distribution with $\mathrm{df}=$ $n-1=52-1=51$. From Table VII, Appendix A, $\chi_{.025}^{2} \approx 71.4202$ and $\chi_{975}^{2} \approx 32.3574$. The rejection region is $\chi^{2}<32.3574$ or $\chi^{2}>71.4202$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=57.740 \ngtr 71.4202$ and $\left.\chi^{2}=57.740 \varangle 32.3574\right), H_{0}$ is not rejected. There is insufficient evidence to indicate the variance of the solution times differ from 2 at $\alpha=.05$.
8.148 a. The hypotheses would be:
$H_{0}$ : Individual does not have the disease
$H_{\mathrm{a}}$ : Individual does have the disease
b. A Type I error would be: Conclude the individual has the disease when in fact he/she does not. This would be a false positive test.
A Type II error would be: Conclude the individual does not have the disease when in fact he/she does. This would be a false negative test.
c. If the disease is serious, either error would be grave. Arguments could be made for either error being graver. However, I believe a Type II error would be more grave: Concluding the individual does not have the disease when he/she does. This person would not receive critical treatment, and may suffer very serious consequences. Thus, it is more important to minimize $\beta$.
8.150 a. To determine if the true mean crack intensity of the Mississippi highway exceeds the AASHTO recommended maximum, we test:

$$
\begin{aligned}
& H_{0}: \mu=100 \\
& H_{a}: \mu>100
\end{aligned}
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{.210-.100}{\sqrt{.011} / \sqrt{8}}=2.97$
The rejection region requires $\alpha=.01$ in the upper tail of the $t$ distribution with $\mathrm{df}=$ $n-1=8-1=7$. From Table VI, Appendix A, $t_{01}=2.998$. The rejection region is $t>2.998$.

Since the observed value of the test statistic does not fall in the rejection region ( $t=2.97 \ngtr 2.998$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the true mean crack intensity of the Mississippi highway exceeds the AASHTO recommended maximum at $\alpha=.01$.
b. A Type I error is rejecting $H_{0}$ when $H_{0}$ is true. In this case, it would be concluding that the true mean crack intensity of the Mississippi highway exceeds the AASHTO recommended maximum when, in fact, it does not.

A Type II error is accepting $H_{0}$ when $H_{0}$ is false. In this case, it would be concluding that the true mean crack intensity of the Mississippi highway does not exceed the AASHTO recommended maximum when, in fact, it does.
8.152 a. To determine if the variance of the weights of parrotfish is less than 4 , we test:

$$
\begin{aligned}
& H_{0}: \sigma^{2}=4 \\
& H_{\mathrm{a}}: \sigma^{2}<4
\end{aligned}
$$

The test statistic is $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{(10-1) 1.4^{2}}{4}=4.41$

The rejection region requires $\alpha=.05$ in the lower tail of the $\chi^{2}$ distribution with $\mathrm{df}=$ $n-1=10-1=9$. From Table VII, Appendix A, $\chi_{95}^{2}=3.32511$. The rejection region is $\chi^{2}<3.32511$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=4.41 \nless 3.32511$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the variance of the weights of parrotfish is less than 4 at $\alpha=.05$.
b. We must assume that the weights of the parrotfish are normally distributed.
8.154 a. A Type II error would be concluding the mean amount of PCB in the effluent is less than or equal to 3 parts per million when, in fact, it is more than 3 parts per million.
b. From Exercise 8.153, $z=\frac{\bar{x}_{0}-\mu_{0}}{\sigma / \sqrt{n}} \Rightarrow \bar{x}_{0}=z \frac{\sigma}{\sqrt{n}}+\mu_{0} \Rightarrow \bar{x}_{0}=2.33 \frac{.5}{\sqrt{50}}+3 \Rightarrow \bar{x}_{0}=3.165$ For $\mu=3.1, \quad \beta=P(\bar{x} \leq 3.165)=P\left(z \leq \frac{3.165-3.1}{\frac{.5}{\sqrt{50}}}\right)=P(z \leq .92)=.5+.3212=.8212$
(from Table IV, Appendix A)
c. Power $=1-\beta=1-.8212=.1788$
d. For $\mu=3.2, \beta=P(\bar{x} \leq 3.165)=P\left(z \leq \frac{3.165-3.2}{\frac{.5}{\sqrt{50}}}\right)=P(z \leq-.49)=.5-.1879=.3121$

$$
\text { Power }=1-\beta=1-.3121=.6879
$$

As the plant's mean PCB departs further from 3, the power increases.
8.156 The point estimate for $p$ is $\hat{p}=\frac{x}{n}=\frac{71+68}{678}=\frac{139}{678}=.205$

In order for the inference to be valid, the sample size must be large enough. The sample size is large enough if both $n p_{\mathrm{o}}$ and $n q_{\mathrm{o}}$ are greater than or equal to 15 .
$n p_{\mathrm{o}}=678(.25)=169.5$ and $n q_{0}=678(1-.25)=678(.75)=508.5$. Since both of these values are greater than 15 , the sample size is large enough to use the normal approximation.

To determine if the true percentage of appealed civil cases that are actually reversed is less than $25 \%$, we test:

$$
\begin{aligned}
& H_{0}: p=.25 \\
& H_{\mathrm{a}}: p<.25
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{.205-.25}{\sqrt{\frac{.25(.75)}{678}}}=-2.71$
The rejection region requires $\alpha=.01$ in the lower tail of the $z$ distribution. From Table IV, Appendix A, $z_{01}=2.33$. The rejection region is $z<-2.33$.

Since the observed value of the test statistic falls in the rejection region $(z=-2.71<-2.33)$, $H_{0}$ is rejected. There is sufficient evidence to indicate the true percentage of appealed civil cases that are actually reversed is less than $25 \%$ at $\alpha=.01$.
8.158 Assume that the pressure reading is a normal random variable and the sample is random. If the new instrument is more reliable, its variance will be less. We test:

$$
\begin{array}{ll}
H_{0}: & \sigma^{2}=10.3 \\
H_{\mathrm{a}}: & \sigma^{2}<10.3
\end{array}
$$

Test statistic $\chi^{2}=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}=\frac{4(9.8)}{10.3}=3.81$
The rejection region requires $\alpha=.05$ in the lower tail of the $\chi^{2}$ distribution with $\mathrm{df}=n-1$ $=5-1=4$. From Table VII, Appendix A, $\chi_{95}^{2}=.710721$. The rejection region is $\chi^{2}<.710721$.

Since the observed value of the test statistic does not fall in the rejection region ( $\chi^{2}=3.81 \nless .710721$ ), $H_{0}$ is not rejected. There is insufficient evidence to indicate that the variance is less for the new instrument at $\alpha=.05$.
8.160 To refute the claim that $60 \%$ of parents with young children condone spanking their children as a regular form of punishment, we test:

$$
\begin{aligned}
& H_{0}: p=.6 \\
& H_{\mathrm{a}}: p \neq .6
\end{aligned}
$$

The test statistic is $z=\frac{\hat{p}-p_{0}}{\sqrt{\frac{p_{0} q_{0}}{n}}}=\frac{\hat{p}-.6}{\sqrt{\frac{.6(.4)}{100}}}=\frac{\hat{p}-.6}{.049}$
No value was given for $\alpha$. We will use $\alpha=.05$. The rejection region requires $\alpha / 2=.05 / 2=.025$ in each tail of the $z$ distribution. From Table IV, Appendix A, $z .025=$ 1.96. The rejection region is $z<-1.96$ or $z>1.96$.

To find the number of parents who would need to say they condone spanking to refute the claim, we will set the value of the test statistic equal to the $z$-values associated with the rejection region.

$$
\frac{\hat{p}-.6}{.049} \leq-1.96 \Rightarrow \hat{p}-.6 \leq-.096 \Rightarrow \hat{p} \leq .504 \Rightarrow \frac{x}{100} \leq .504 \Rightarrow x \leq 50
$$

and

$$
\frac{\hat{p}-.6}{.049} \geq 1.96 \Rightarrow \hat{p}-.6 \geq .096 \Rightarrow \hat{p} \geq .696 \Rightarrow \frac{x}{100} \geq .696 \Rightarrow x \geq 70
$$

Thus, to refute the claim, we would need either 50 or fewer parents to say they condone spanking or 70 or more parents to say they condone spanking to refute the claim at $\alpha=.05$.
8.162 Some preliminary calculations are:

$$
\begin{array}{ll}
\bar{x}=\frac{\sum x}{n}=\frac{110}{5}=22 \quad s^{2}=\frac{\sum x^{2}-\frac{\left(\sum x\right)^{2}}{n}}{n-1}=\frac{2,436-\frac{110^{2}}{5}}{5-1}=4 \\
s=\sqrt{s^{2}}=\sqrt{4}=2
\end{array}
$$

To determine if the data collected were fabricated, we test:

$$
\begin{aligned}
& H_{0}: \mu=15 \\
& H_{\mathrm{a}}: \mu \neq 15
\end{aligned}
$$

The test statistic is $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}=\frac{22-15}{2 / \sqrt{5}}=7.83$
If we want to choose a level of significance to benefit the students, we would choose a small value for $\alpha$. Suppose we use $\alpha=.01$. The rejection region requires $\alpha / 2=.01 / 2=.005$ in each tail of the t distribution with $\mathrm{df}=n-1=5-1=4$. From Table VI, Appendix A, $t_{.005}=4.604$. The rejection region is $t<-4.604$ or $t>4.604$.

Since the observed value of the test statistic falls in the rejection region $(t=7.83>4.604), H_{0}$ is rejected. There is sufficient evidence to indicate the mean data collected were fabricated at $\alpha=.01$.
